**Abstract**

**Background:** Oxidative stress and dyslipidemia play a critical role in the development of cardiovascular disease. Regular intake of polyphenol-rich diets is associated with a reduced risk of cardiovascular diseases.

**Methods:** The present study was a pilot study with 24 healthy volunteers and was designed to determine if a 12-week administration of *Cistus incanus* herbal tea, containing phenolic acids and flavonoids, reduces cardiovascular risk factors including oxidative stress and dyslipidemia in healthy adults. Phenolic compounds profile and antibacterial activity of *Cistus incanus* infusion were also measured.

**Results:** Herbal infusion led to improvement in lipid profile by increase (Δ4%, p = 0.033) high-density lipoprotein cholesterol concentration and decrease triglyceride (Δ14%, p =
concentrations. In addition, the Cistus incanus diet was associated with decreased serum concentrations of malondialdehyde (Δ16%, p < 0.01) and advanced oxidation protein products (Δ18%, p < 0.001).

**Conclusions:** Cistus incanus administration decreases cardiovascular risk factors including oxidative stress and dyslipidemia and this action supports the idea of using Cistus incanus tea on a daily basis as an effective dietary component for prevention of atherosclerotic cardiovascular disease.

**Keywords:** Cistus incanus, lipid profile, oxidative stress markers

**Introduction**

*Cistus incanus*, a genus belonging to the family of Cistaceae, provides a rich source of polyphenols and various Cistus species herbal teas have been used in folk medicine for treatment of diarrhea, fever, and skin disorders. It also has antispasmodic, anti-inflammatory and antimicrobial agents [1]. Currently, numerous producers offer Cistus incanus herbal infusion (Cistus tea) or dietary supplements consisting of this plant material, or extracts of it. These products are especially promoted with regard to a high content and diverse profile of polyphenolic substances with strong antioxidant activity [2]. It has been proposed that polyphenols can act as antioxidants by suppression of reactive species formation through enzyme inhibition or the sequestration of trace elements involved in the production of free radicals [3]. Reactive oxygen species are involved in pathogenesis of diverse human diseases which play a particular role in cardiovascular diseases [4, 5]. Polyphenols are able to attenuate the oxidation of low-density lipoproteins, possess vasodilatory and anti-inflammatory activity, and modulate lipid metabolism and apoptotic processes in endothelium [6]. It has been suggested that most of these effects are a consequence of the antioxidant properties of polyphenols; however, other mechanisms based on their interaction with molecular signaling pathways may be involved [2, 7].

Epidemiological studies provide evidence for an inverse relationship between the consumption of polyphenolic substance-rich foods and cardiovascular complications [8]; however, most of the epidemiological studies aimed at investigating cardiovascular benefits of polyphenols have concerned tea, red wine, coca and polyphenol-rich fruits such as grapes. Furthermore, although there are numerous studies evaluating the composition and antioxidant capacities of Cistus infusion, however, clinical studies focused on the influence of Cistus incanus on oxidation balance and cardiovascular risk factors are limited [9]. Thus, the purpose
of the present study was to investigate the impact of a 3-month supplement of commercially available *Cistus incanus* tea on oxidative stress markers and lipid profile in healthy adults. Additionally, the phenolic compounds profile was determined as well as antibacterial activity of when using *Cistus incanus* aqueous infusions.

**Methods**

**Study subjects**

A total of 24 healthy adults were recruited for the study. All procedures performed in studies involving human participants were in accordance with the 1964 Helsinki declaration and were approved by the Medical Ethics Committee of Medical University of Gdansk. All participants provided written informed consent.

During the interview, sociodemographic and clinical information was collected. The sociodemographic data included age, and gender. Clinical variables included vascular risk factors: smoking status, alcohol intake, physical activity, lifestyle, and dietary habits. All participants were non-smoking and were sedentary or moderately physically active (at least 2 times a week). All volunteers were instructed not to change their diet or physical activity during the study. The exclusion criteria were: chronic disease, current use of prescribed pharmaceuticals, intense physical activity (up to 3 times a week) and a body mass index (BMI) greater than 25 kg/m². The study period was 12 weeks, during which participants would intake a *Cistus incanus* infusion 3 times a day (portion of 2 g of dry tea per day reinfused 3 times in 250 mL of boiling water for 3 min). Dietary compliance was assessed using daily study records completed by the participants.

**Analysis of blood samples from subjects**

The peripheral fasting blood samples were collected before (baseline) and after 6 and 12 weeks of *Cistus incanus* infusion administration. The serum was separated by centrifugation at 1000×g for 15 min and stored at −80°C pending analysis. Total cholesterol (TC) and triglycerides (TG) were measured by standard enzymatic colorimetric tests (Pointe Scientific Poland). High density lipoproteins (HDLs) were isolated by precipitation of apolipoprotein B (apoB)-containing lipoproteins with dextran sulfate 50000/Mg²⁺ reagent and HDL cholesterol (HDL-C) was determined enzymatically. Low density lipoprotein cholesterol (LDL-C) concentration was calculated using the Friedewald formula. Paraoxonase (PONase) and arylesterase (AREase) activities of paraoxonase-1 (PON-1) were measured based on paraoxon and phenyl acetate hydrolysis, respectively [10, 11]. Malondialdehyde
(MDA) concentration was analyzed by fluorescence spectroscopy using a modified thiobarbituric acid-reactive substance [12]. Advanced oxidative protein product (AOPP) determination was performed based on spectrophotometric detection [13].

**Plant material**

The *Cistus incanus* herb was purchased from a manufacturer in Poland (herbal manufacture ASTRON Józef Tabor). According to the manufacture information, the shrub grows in the Mediterranean Region of Turkey around the city of Antalya, and the shrub’s leaves are harvested from May to August.

**Determination of total polyphenols and antioxidant activity**

The leaves (1.00 g) were brewed with 100 mL of boiling and deionized water for 15 min and the procedure was repeated two times to finally produce the first, second and third infusion. The Folin-Ciocalteu method was used for total phenolic content (TPC) determination [14]. The method described in the European Pharmacopoeia monograph for *Betulae* folium was used for total flavonoid content (TFC) determination [15]. The total phenolic acid content was determined using the spectrophotometric method with Arnow’s reagent according to procedures described in the Polish Pharmacopoeia [16]. L-ascorbic acid (AA) was determined by spectrophotometric method [17]. 2,2-diphenyl-1-picrylhydrazyl radical (DPPH) scavenging assay [18] and ferric ion reducing antioxidant power (FRAP) assay [19] were used to determine the reducing antioxidant power of the *Cistus incanus* infusions.

**Chromatographic analysis: HPLC conditions**

Before HPLC analysis, all the infusions were filtered through a 0.2 μm nylon filter film (Mecherey, Nagel, Germany) and 20 μL of the filtrate was injected into the HPLC system. Chromatographic separation and quantitation of phenolic compounds (gallic, caffeic, chlorogenic, syringic, vanillic, p-coumaric, elagic and ferulic acids, and rutin, isoquercetin, quercetin, myricetin, kaempferol, and luteolin 7-glucoside) were performed on a Hypersil Gold C18 column (250 × 4.6 mm, 5 μm particles, Thermo Scientific, Runcorn, UK) maintained at 35°C, using acetonitrile — 0.2% trifluoroacetic acid solution and water — 0.2% trifluoroacetic acid solution as the mobile phase using a gradient program and monitoring system as previously described [20].
**Antibacterial activity**

A sample of *Cistus incanus* (2.5 g) was infused three times with 50 mL of boiling, deionised water for 15 min to produce the first, second, and third infusion. The minimal inhibitory concentration (MIC) and minimal bactericidal concentration (MBC) of all the infusions were assessed by the micro-broth dilution method according to the EUCAST (European Committee for Antimicrobial Susceptibility Testing) and CLSI (Clinical and Laboratory Standards Institute) reference procedures. Assays were carried out against selected reference and clinical strains Gram-positive: *Staphylococcus aureus* ATCC 6538, methicillin-resistant *Staphylococcus aureus* 12,673 (clinical isolates), *Staphylococcus epidermidis* ATCC 14,990, methicillin-resistant *Staphylococcus epidermidis* (clinical isolates), *Streptococcus pneumoniae* (clinical isolates), *Bacillus subtilis* ATCC 6633, and Gram-negative bacteria *Escherichia coli* ATCC 8739. Clinical isolates were obtained from St. Albert Specialist Hospital in Gdansk (Independent Public Health Care Facility in Gdansk, Poland).

**Statistical analysis**

Statistical analysis was performed using the Statistica software package (STATISTICA 12.0 Statsoft Poland). The Shapiro-Wilk test was used to establish data distributions. Continuous variables were expressed as a mean ± standard deviation or median with 25th and 75th percentiles (interquartile range [IQR]). Potential differences among the results were analyzed using a repeated-measures ANOVA with the Tukey multiple comparison test for parametric variables and with the Friedman test for non-parametric data. Statistical significance was set at p < 0.05.

**Results**

The study participants were aged between 23 and 25 years old (21 females and 3 males) with a body mass index (BMI) of 21.3 ± 0.6 kg/m². There were no significant differences in BMI during the 12-week period of dietary modification.

**Lipid profile and serum oxidative stress parameters**

Analysis of the lipid profile revealed a significant increase in HDL-C concentration (47 ± 9 vs. 50 ± 9 mg/dL; p = 0.033) and a decrease in TG levels (71 ± 23 vs. 60 ± 24 mg/dL; p = 0.013), there were no changes in the concentration of TC and LDL-C over 12 weeks of follow up (Fig. 1). The concentrations of serum oxidative stress markers — MDA and AOPP were measured before and after 6 and 12 weeks of *Cistus incanus* herbal tea supplementation.
A reduction of about 16% in MDA concentration (20 ± 5.5 vs. 15 ± 4.9 μmol/L; p < 0.01) and 18% in AOPP concentration (66 ± 18 vs. 53 ± 17 μmol/L; p < 0.001) after the first 6 weeks of Cistus incanus intake was observed (Fig. 2). The following 6 weeks of supplementation showed no further significant changes in concentrations of MDA (15 ± 4.9 vs. 15 ± 4.5 μmol/L) and AOPP (53 ± 17 vs. 54 ± 16 μmol/L). There was no significant effect of Cistus infusion on paraoxonase-1 activities, measured both toward paraoxon and phenyl acetate as substrates (Table 1).

**Phenolic content and antioxidant capacity**

Total phenolic acids (TPC), flavonoids (TFC), phenolic acids (TPAC) and L-ascorbic acid (AA) contents in multiple aqueous extractions of Cistus incanus were determined, the results are presented in Table 2. Analysis of variance and the Duncan multiple range test indicate a significant influence of multiple extractions (p < 0.05) on TPC, TFC, TPAC, and AA. The effects of multiple extractions on the phenolic acids and flavonoids content of Cistus infusions are presented in Table 3 and 4, respectively. Among phenolic acids the most abundant was gallic acid. Caffeic and vanilic acids were determined only in the first extraction, while chlorogenic, syringic and ferulic acids were not found. In the case of flavonoids, myricetin and isoquercetin were the most abundant, while keampferol was not determined. According to the TPC, TFC, TPAC and AA the content of phenolic acids and flavonoids also gradually decreased and the lowest content was obtained in the third extract of Cistus infusions. The antioxidant capacities of Cistus incanus evaluated by DPPH and FRAP assays exhibited a gradual decrease and the lowest activity was obtained in the third extract of Cistus infusions (Table 5).

**Antibacterial activity**

To investigate the possible antibacterial activity of aqueous Cistus incanus, Gram-positive and Gram-negative bacteria strains were used. The values of MIC and MBC are shown in Table 6. For all Gram-positive bacteria, the MIC value was 4 mg/mL and the MBC ranged from 8 to 32 mg/mL, suggesting a bacteriostatic effect. There was no difference in antimicrobial activity of the extracts between successive infusions. No activity was demonstrated against Gram-negative bacteria in the tested concentration range.

**Discussion**
The presented results demonstrate that systematic administration of aqueous extract of *Cistus incanus* influences the lipid profile in healthy adults. According to available research, this is the first study to investigate any association between a serum oxidative stress biomarker and a *Cistus incanus* tea-rich diet. The in vivo studies of biological activity of polyphenols seem to be especially important because polyphenols are extensively metabolized in the body and their bioavailability may be different. Thus, the relation between the quantity of polyphenols in food and their in vivo activity is not obvious [7, 21].

Excessive uncontrolled lipid and protein oxidation is associated with pathogenesis of various diseases such as atherosclerosis, osteoporosis, cancer, Alzheimer’s, and Parkinson’s diseases. Among them atherosclerosis is the underlying condition in most cardiovascular diseases being the leading cause of death in Western societies. Oxidation of low-density lipoproteins is a key mechanism in this chronic systematic disease, leading to the development and progression of the disease. A number of animal studies have demonstrated that consumption of polyphenols limits the incidence of coronary heart disease and an abundance of literature has shown that polyphenols effectively protect LDL against oxidation *ex vivo* [4, 5, 22]. In the present study, assessing the effect of herbal supplements on oxidative stress parameters, it was found that the concentration of MDA as a marker of lipid peroxidation, and AOPP as a marker of protein peroxidation, decreased significantly after 6 weeks of use. Data in the literature concerning the impact of phenolic compounds from *Cistus incanus* extract on oxidative balance is poor. However, the increase in antioxidative capacity of plasma following the consumption of other polyphenol-rich food has been widely described. Leenen et al. [23] showed that even a single dose of tea with or without milk increases plasma antioxidant activity. Increased antioxidative capacity was also observed as a consequence of the systematic intake of wine and beer, as well as fruit and vegetables rich in polyphenols such as strawberries and spinach [2]. It has also been shown that the consumption of polyphenol-rich blackcurrant and apple juice by healthy volunteers significantly reduced the plasma concentrations of MDA [24]. However, data from the impact of red wine consumption on lipid peroxidation is ambiguous [25–27].

Potent inhibition of LDL oxidation is, however, not only suggested by the protective effects of polyphenols against cardiovascular disease. Polyphenols have also been shown to inhibit the invasion and proliferation of smooth muscle cells in the arterial wall, inhibit platelet aggregation, and improve endothelial dysfunction in animal models [28, 29]. Polyphenols may also modify the lipid profile. A significant increase in plasma HDL-C was observed in healthy adults when administered drinks containing coca for 12 weeks [30].
Administration of Bergamot polyphenol extract for 30 days also resulted in increased HDL-C and decreased triglyceride concentrations in hyperlipidemic patients [31]. Data from the study about rich-in-polyphenol teas are, however, contradictory. One meta-analysis found no effects of black tea on TC and serum concentrations of LDL-C and HDL-C [32], while another concluded that consumption of black tea lowered LDL-C, especially in subjects at high cardiovascular risk [33]. In the current study a significant increase in HDL-C concentration was observed and a decrease in TG level during a three-month supplementation with Cistus incanus was also recorded. These results suggest a positive impact on lipid metabolism and confirms a very wide range of potential pro-health attributes of Cistus incanus.

Several studies have attempted to elucidate the phenolic composition of Cistus incanus [34–37]. Viapiana and Wesolowski [20] in their earlier work assessed the phenolic profile and antioxidant capacity of aqueous extract of 15 commercially available samples of Cistus incanus, and showed that the place of the origin was the main factor in differentiating the Cistus incanus samples. The extracts obtained from Turkish Cistus incanus were the richest in total phenolic compounds (TPC), flavonoids (TFC), phenolic acid (TPAC) and ascorbic acid (AA). Cistus incanus used in the present study came from Mediterranean part of Turkey around the city of Antalya and — similar to previously analyzed samples from Turkish Cistus incanus — myricetin, quercetin, and isoquercetin were the most abundant phenolic compounds, with a content exceeding 800 μg/g dw. Gallic acid and rutin were found at the level ca. 500 μg/g dw, and 7-luteolin glucoside came in ca. 400 μg/g dw.

The antioxidant activities, evaluated with DPPH and FRAP also showed similar results to the previous published range of antioxidative capability of samples from Turkish Cistus incanus [20]. Deng et al. [38] determined the antioxidant capacities and total phenolic contents of 56 vegetables, and the levels of TPC, DPPH and FRAP values were lower than results obtained in this study, which seems to confirm Cistus incanus tea as a good source of polyphenols in the human diet. However, Konieczyński et al. [39] determined individual phenolic compounds in green and black teas and their total levels were higher than that obtained in the Cistus incanus infusions. In earlier studies it was established that aqueous extracts of Cistus exhibit good antimicrobial activity, particularly against bacteria G (+), and to a much lesser extent, affecting the growth of bacteria G (−) [20, 37]. Therefore, in this work it was decided to perform tests mainly in relation to selected G (+) bacteria. The present results confirmed good antimicrobial activity against bacteria G (+). Once again, no activity was demonstrated against G (−) bacteria in the tested concentration range.
According to the commercially included instructions, volunteers participating in the project reinfused the daily portion of *Cistus incanus* 3 times. The study of the multiple extractions effect on the phenolic acids and flavonoids content revealed that *Cistus incanus* tea can be re-infused; however, the first infusion showed higher levels of polyphenols and antioxidant activities, which gradually decreased in later infusions. There was no difference in antimicrobial activity of the extracts on successive infusions.

**Conclusions**

This study supports the idea that *Cistus incanus* tea can be a valuable source of polyphenols in the human diet. The supplementations with the commercially available Turkish *Cistus incanus* tea had a positive impact on oxidative stress markers and lipids profile, allowing us to suggest that there are a wide range of pro-health properties of *Cistus incanus*, and beneficial effects on the cardiovascular system may be added.
