The world is currently struggling with a pandemic of novel enveloped RNA beta-coronavirus, which has currently been named severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), which has a phylogenetic similarity to SARS-CoV and the disease it caused has been called COVID-19.

The COVID-19 can present as an asymptomatic carrier state, acute respiratory disease, and pneumonia [1]. As of April 1, 2020, a total of 1017,693 laboratory-confirmed cases had been documented globally, including more than 53,179 deaths have been reported worldwide. Given the rate of infected people, SARS-CoV-2 is a highly contagious virus which is mainly spread through close contact with infected people via respiratory droplets from cough or sneezing. Wei et al. [2] indicated that several public health measures that may prevent or slow down the transmission of the COVID-19 were introduced; these include case isolation, identification and follow-up of contacts, environmental disinfection, and use of personal protective equipment.

World Health Organization recommends against routinely wearing masks in community settings because of lack of evidence [3]. However, the lack of scientific evidence should not discourage people from wearing disposable face masks

to limit droplet spread [4, 5]. Routine wearing of disposable masks by everyone as a public health intervention, would probably intercept the transmission link and prevent these apparently healthy infectious sources. Masks can be divided into two main groups: medical (surgical) masks and N95 respirators (designed during a pandemic mainly for high-risk medical personnel). Global shortage of medical masks is a real and expanding problem. In turn, there is growing availability on the market of cloth masks, which were used by surgeons successfully during operations before disposable masks were available. As indicated in the research published by MacIntyre et al. [6] in a study on the comparison of the efficacy of cloth masks to medical masks in the context of viral infections in hospital healthcare workers, summarized that cloth masks don't protect as well as medical masks (Fig. 1). Laboratory tests showed the penetration of particles through the cloth masks to be very high (97%) compared with medical masks (44%). A consequence of the above penetration is also a higher risk of critical care illness, the influenza-like illness is more significant in the cloth mask group than in the medical mask. Moreover, the rate of confirmation of laboratory-confirmed viruses was also much higher for cloth masks than for medical masks or groups that did not wear any mask.

Figure 1. Results of meta-analysis determine effectiveness of medical masks versus cloth masks against respiratory infection. Outcomes are: clinical respiratory illness (A), influenza-like illness (B), laboratory-confirmed viruses (C); CI — confidence interval.

In the era of this deficit of masks, another problem arises, to which particular attention should be paid. Most people in all seriously affected areas are reusing their disposable masks. The physical properties of a cloth mask, reuse, the frequency and effectiveness of cleaning, and increased moisture retention, may potentially increase the infection risk, since, as it indicated by Osterholm et al. [7] the virus may survive on the surface of the face-masks. In this context self-contamination through repeated use and improper doffing is possible. Observations during SARS suggested double-masking and other practices increased the risk of infection because of moisture, liquid diffusion and pathogen retention [8].
