Abstract

Duplication of the spleen, classified as a polysplenia syndrome, is a very rare anomaly. Polysplenia is a complex syndrome with a broad spectrum of abnormalities. Other abnormalities accompanying polysplenia have been previously reported. In this paper, we present a case of duplication of the spleen accompanied by multiple anomalies in the thorax and abdomen.

Key words: spleen, duplication, computed tomography
INTRODUCTION

Duplication of the spleen is a rare seen anomaly which is classified in polysplenia syndrome. Polysplenia refers to the situation in which the splenic tissue is divided into two or more equal parts [4]. It is often associated with various visceral anomalies [4]. Polysplenia is a rare embryological disease reported in 1 in 250,000 people, resulting from failure in the development of normal asymmetry of left-right visceral organs [8]. Genetic studies showed that polysplenia is multifactorial inheritance [16]. Polisplenia is reported more frequently in women [1]. It must be distinguished from accessory spleen which defines the situation in which a normal sized spleen and one or more small spleen tissues are present [4]. Kim et al. used the duplication of the spleen term to express similarly shaped splenic tissues that have their own arteries and veins [7].

In this paper, we present a case of duplication of the spleen accompanied by new thoracic and abdominal anomalies.

CASE REPORT

In April 2018, a 44-year-old female patient presented to the emergency department with sudden onset of left sided chest pain. She denies any fever, cough, shortness of breath. The patient had no pain with palpation and coughing. The physical exam is completely normal including auscultation of the heart and lungs. Vital signs were stable. Common causes of sudden chest pain were investigated (Table 1). Chest x-ray was unremarkable. ECG and cardiac enzymes were in the normal range. Echocardiographic measurements were within standard normal limits. CT angiography showed pseudocoarctation of the aorta characterized by kinking and poststenotic dilatation at the isthmus level of the aorta (Figure 1a, Figure 1e). Azigos veni dilateydi (Figure 1b, Figure 1c). The position of the heart was normal. Indentation of the aorta to the trachea was observed (Figure 1d). Both lungs were bilobulated. Inferior vena cava (IVC) showed continuity with the dilated azygos vein at the entrance into the thorax after the inclusion of the left retro-aortic renal vein and right renal vein (Figure 1f). The hepatic veins were opened directly into the right atrium. At CT examination, contrast phase was not sufficient to evaluate pulmonary embolism. When D-Dimer elevation and thrombosis consistent with acute
deep vein thrombosis (DVT) were detected in the left lower extremity veins, the patient was evaluated as pulmonary embolism and treated.

She was admitted to our hospital with pelvic pain in September 2019. Physical examination revealed tenderness in the pelvic region. Complete blood count revealed leukocytosis and ultrasound shown a complicated cystic lesion in the left ovary. Abdominal contrast enhanced CT revealed a 4 cm large cyst in the left ovary and contamination of the surrounding fatty tissue so the patient was diagnosed as pelvic inflammatory disease. In addition, two spleens of ~9x4 cm and ~9.5x3.5 cm in size located in the superior and inferior aspects, respectively. There was a characteristic staining of a zebra pattern in the abdominal sections of the images. The two spleens had their own vascular structures (Figure 2a, Figure 2b). They were also in close proximity to each other, but had not merged. Both spleens were supplied from the splenic artery branches and their venous drainage was to the splenic vein. In our case, the splenic artery had emerged from the celiac truncus and with significant tortiosity in the distal half, was sending the lateral branch to the superior spleen first. This side branch was then divided into end branches extending to the upper and middle portions of the upper spleen. The terminal part of the splenic artery was divided into two end branches feeding the upper and lower poles of the lower spleen and a third end branch feeding the lower pole of the upper spleen. The splenic vein first emerged from the spleen located on the lower side and then drained from the upper spleen and formed the superior mesenteric vein and portal vein. Unusually, the distal half of the splenic vein was tortiosed.

Rather than the classic “J” shape, the pancreas was ovoid in appearance, with the body being thicker than the head. The pancreatic tail ended at the level of the medial half of the left kidney (figure 2c). The colon segments were located in the left half of the abdomen (Figure 2d).

**DISCUSSION**

Duplication of the spleen can be confused with splenic cleft, splenic lobulation, and an accessory spleen. However, in cases with splenic duplication, both spleens have their
own vascular structures, and the don’t merge of each spleen allows for the
differentiation between these three variations.

Duplication of the spleen was first described in 2009 by Kim et al, on abdominal CT to
investigate metastasis in a 71-year-old male patient with small cell lung cancer [7]. This
patient also had short pancreas and preduodenal portal vein. In our case, there is also a
short pancreas which has also been reported in other polysplenia syndromes [5, 12, 15].
Later in 2013, Sharma et al. reported a 43-year-old male patient presenting with upper
gastrointestinal bleeding [13]. In this case, the reason of bleeding was the varicose veins
due to the abnormal venous drainage of the upper part of the spleen to the gastric
fundus veins. Endoscopy, endosonography, angiography and CT findings were reported
without any additional visceral anomalies. Finally, in 2014, Paramasivam et al. reported
the cadaveric findings of a 60-year-old man [9].

Duplication of the spleen is classified in polysplenia syndrome with accompanying
similar pathologies.

Gastrointestinal system anomalies, liver anomalies, and IVC anomalies have been
described in patients with polysplenia [3]. In a study, 7 of 8 patients with polysplenia
were reported to have continuous IVC with azygos vein [3]. Azygos continuation of the
inferior vena cava is the most common anomaly seen in polysplenia syndromes [3]. The
coexistence of aortic pseudocoarctation and polysplenia has also been previously
reported [2, 11], which is consistent with the kink and poststenotic dilatation observed
at the aortic isthmus level in the current case. The left retro-aortic renal vein is usually
isolated.

Embryologically, the left renal vein normally develops from inter-subcardinal
anastomosis [6] while the retro-aortic vein develops from inter-supracardinal
anastomosis and accompanies azygos continuation of IVC and polysplenia [14].
Bilobulated right lung has been described in patients with polysplenia and occurs in
slightly more than half of the cases [10]. Polysplenia generally is associated with
intestinal malrotation [3] and also in our case intestinal malrotation has been presented.

In conclusion, our case of duplication of the spleen showed similar aortic, IVC,
pulmonary, pancreatic, and intestinal abnormalities to other polysplenia syndromes. The
presence of multiple anatomical anomalies in this patient groups important in the planning of surgical and interventional procedures in order to avoid undesirable outcomes.
