Percutaneous coronary interventions (PCI) have an established position in the management of patients presenting with acute coronary syndromes [1]. Rare, but serious adverse events may be related to stents/wire distortions [2, 3].

We present a case of a 67-year-old male who was admitted to a hospital with anterior wall ST-elevation myocardial infarction. Urgent coronary catheterization revealed left anterior descending artery (LAD) occlusion close to diagonal branch origin (Figure 1A). Middle segments of circumflex (CX) and right coronary (RCA) arteries were also significantly stenotic (Figure 1B). The heart team decided to perform emergent LAD angioplasty.

The bolus of 7.9 ml of INN-eptifibatide was administrated and followed by continuous infusion with a 14 ml/h rate. The drug-eluting stent (Xience 3.0 × 28 mm) was implanted into LAD. After stent implantation, a part of the wire was entrapped in the coronary artery. The metallic coil covering the core of the angioplasty wire was left in the proximal part of LAD and protruded into the aortic root. The saphenous vein bypass grafts (SVBG) were performed into CX and RCA and the left internal mammary (LIMA) was anastomosed into LAD with continuous 7-0 monofilament suture. The estimated blood flow was 7 ml/min with pulsation index (PI) of 3.4 in LIMA-to-LAD 39 ml/min with PI 1.3 in SVBG-to-CX and 43 ml/min with PI 1.1 in SVBG-to-RCA grafts, respectively.

The surgical approach allows achieving complete revascularization in acute coronary syndromes. Postoperative bypass blood flow measurements provide significant information about the quality of performed anastomoses.
