Abstract

Struma ovarii is a rare form of ovary tumour defined as the presence of ectopic thyroid tissue in the ovarian structures. It usually presents with a benign course, although in some cases carcinoma or other malignant tumours can be found in the context of the ectopic tissue. Herein we report the case of a young patient affected by struma ovarii visualized by means of 124I-Na PET/CT. Thanks to the excellent target-to-background ratio of the tracer and the high resolution of the method, we could well identify the presence of some minimal tumour at the level of the left ovary. To our knowledge, this is the first report of its kind.

Case report

Struma ovarii is a rare form of ovary tumour, accounting for 1% of the ovarian neoplasia, and defined as the presence of ectopic thyroid tissue in the ovarian structures [1]. It usually presents with a benign course, although in some cases carcinoma or other malignant tumours can be found in the context of the ectopic tissue [2, 3].

Herein we report the case of a young patient affected by struma ovarii, which was incidentally diagnosed during a caesarean delivery. Our 29 year-old patient had the removal of an ovarian cyst during the delivery and histology showed a well-differentiated papillary carcinoma of thyroid origin. Specific investigations of the thyroid gland, including ultrasound, made the possibility of malignant transformation of the eutopic tissue unlikely, thus suggesting that the degeneration found in the struma ovarii had an in-loci origin (non-metastatic). Before undergoing further treatment [4, 5], we decided to perform a total-body PET/CT scan with 124I-Na (Figure 1). Along with the pathologic tracer accumulation, we could also identify some physiologic uptake in the thyroid gland, as well as in the stomach and in the bladder, due to salivary and urinary excretion.
the high resolution of the method (~0.5 cm), we could well identify
the presence of some minimal tumour residue (diameter = 0.6 cm;
ki67 ~25%) at the level of the left ovary (arrow). This could not be
imaginable with other methods, including total-body 123/131-I-Na
scan, because of the suboptimal resolution (1.0–1.5 cm) or CT/MR,
because of the inadequate specificity.

To our knowledge, this is the first report of its kind, document-
ing the presence of struma ovarii by means of 124I-Na PET/CT.
